

## March 18<sup>th</sup> WS: 1016-351: Coverage – 2.4, 2.5: Dr. Chulmin Kim

Name: \_\_\_\_\_

1. Sam and Theresa each roll a die. Whoever gets the higher number wins; if they both roll the same number, neither wins.
  - a. What is the probability that Theresa wins?
  
  
  
  
  
  
  
  
  
  
  - b. If Sam rolls a '3', what is the probability that he wins?
  
  
  
  
  
  
  
  
  
  
  - c. If Sam wins, what is the probability that Theresa rolled a '3'?
  
  
  
  
  
  
  
  
  
  
  - d. What is the probability that they are tied? (They roll the same.)
  
  
  
  
  
  
  
  
  
  
2. **[Incidence of a rare disease]**  $P(\text{individual has the disease}) = .001$ ,  $P(+ | \text{individual actually has the disease}) = .99$ , and  $P(+ | \text{individual actually does not have the disease}) = .02$ . To use Bayes' Theorem, determine the  $P(\text{individual actually has the disease} | +)$ .

3. **[Smarty vs. Dummy]** Brown has recently been hired by a shop down town to help customers with various computer related problems. Lately, two different viruses have been bugging many customers — virus Dummy and virus Smarty. It is estimated that about 65% of the customers with virus problems are bothered by virus Dummy and the remaining 35% by virus Smarty. If the computer is infected by virus Dummy, Brown has a 90% chance of fixing the problem. However, if the computer is infected by the virus Smarty, this chance is only 70%.
- a. If a virus-infected computer is randomly selected from the shop, and we know it was fixed by Brown, what is the probability that it was infected with virus Dummy?
  
  
  
  
  
  
  
  
  
  
  - b. A virus-infected computer is randomly selected from the shop. It is infected with virus Dummy. What is the probability that it cannot be fixed by Brown?
  
  
  
  
  
  
  
  
  
  
  - c. A virus-infected computer is randomly selected from the shop. What is the probability that it is infected with virus Dummy and cannot be fixed by Brown?
